## Dedication

36     This study is dedicated to our loved ones, especially our loving parents, for  
37     their unwavering support throughout our academic journey and our continual  
38     source of inspiration and strength when we were on the verge of giving up.

39     To our dear friends, we are grateful for your warm presence, valuable insights,  
40     and constant encouragement, which helped us complete this study.

41     Finally, to our future selves, may this hard work serve as a testament to the  
42     obstacles you have overcome. Let this milestone remind you to keep learning and  
43     face the future with courage, even if the path is uncertain.

## Acknowledgment

45     We extend our heartfelt gratitude to Dr. Francis D. Dimzon for his patient  
46     guidance throughout this study. His thoughtful mentorship in the field of machine  
47     learning contributed to the foundation and direction of this study.

## Abstract

Internet slang is an informal variation of language that is prominent to the younger generation. Its widespread use has contributed to the generational divide between younger and older generations. This study aimed to develop a translation tool leveraging Large Language Models (LLMs) to bridge this divide. A dataset of Generation Z slang sentences and their formal equivalents was used to fine-tune Zephyr-7B-Beta model. The performance of the fine-tuned model was evaluated against the base model using automatic metrics (BLEU and ROUGE-L) and manual evaluations through online surveys involving Gen Z students. The BLEU and ROUGE-L scores of 0.8151 and 0.8396 respectively, indicates a high degree of similarity between the generated text and the reference, suggesting that the model produces translations that closely match the formal equivalents of the Gen Z slang sentences. Furthermore, manual evaluation results showed that 53.5% of the respondents preferred the translations produced by the fine-tuned model, supporting the results of the automatic metrics. The results suggest that fine-tuning LLMs can significantly improve their ability to translate internet slang into formal English.

# Chapter 1

## Introduction

### 1.1 Overview

Language is how humans communicate and express themselves (Crystal & Robins, 2024). It evolves, adapting to the changing needs of users (Jeresano & Carretero, 2022). New words are borrowed or invented (Mantiri, 2010), and most linguistic changes are initiated by young adults and adolescents (Thump, 2016 as cited in (Jeresano & Carretero, 2022)). The younger generation demographic tends to focus on belonging to self-organized groups of peers and friends, forming what can be described as the “we” generation. Through their interactions, language changes differently, making them remarkably distinct from previous generations.

Slang is a great example of the dynamic nature of language. Slang is an informal language used by people in the same social group (Fernández-Toro, 2016). It serves multiple social purposes: identifying group members, communicating in-

130 formally, and opposing established authority (McArthur, 2003). Slang is highly  
131 contextual and pervasive, even in non-standard English. Its figurative nature and  
132 how it twists the definitions of the words used make it difficult for outsiders to  
133 understand.

134 In recent years, the Internet has become a significant medium for the evolution  
135 and spread of language, giving rise to ‘Internet slang’ (J. Liu, Zhang, & Li, 2023).  
136 Internet slang is a collection of everyday language forms used by various online  
137 groups (Barseghyan, 2014). Ujang et al. (2018, as cited in (binti Sabri, bin Ham-  
138 dan, Nadarajan, & Shing, 2020)) state that internet slang is not easily understood  
139 by people outside the social group or people who are not fluent in the language  
140 where the slang is used. This phenomenon is particularly prominent among the  
141 younger generation (Maulidiya, Wijaya, Mauren, Adha, & Pandin, 2021), where  
142 they use it to communicate and interact with friends.

143 Generation Z, individuals born between 1996 and 2009, are regarded as “digital  
144 natives” because technology is an integral part of their upbringing (Dua et al.,  
145 2024). Even the language of this generation is greatly affected by technology,  
146 where newly coined terms and phrases, called Gen Z slang, are tied to the me-  
147 dia culture they’ve grown up with (Jeresano & Carretero, 2022). However, this  
148 evolution of language often creates communication barriers with older generations  
149 (Venter, 2017 as cited in (Ghazali & Abdullah, 2021)). Furthermore, studies show  
150 that even within Generation Z, people with limited exposure to social media may  
151 struggle to understand the prevalent slang (Vacalares, Salas, Babac, Cagalawan,  
152 & Calimpong, 2023).

153 These gaps highlight the need for a tool that can bridge the generational divide,

154 making it easier for individuals to understand the language of Generation Z. Mul-  
155 tiple studies have tried translating slang into a formal language using machine  
156 learning. Khazeni et al. achieved a 81.91% accuracy in translating Persian slang  
157 to formal Persian language using deep learning. Another study by Nocon et al.  
158 created a translator to translate Filipino colloquialisms into the Filipino language  
159 using Tensorflow's sequence-to-sequence model and Moses' phrase-based statis-  
160 tical machine translation. Furthermore, Ibrahim and Sharief developed a slang  
161 translator using models from Hugging Face.

162 Building on these studies, this study created a translation tool specifically to  
163 translate Gen Z slang. The tool will utilize Low Rank Adaptation (LoRA) to a  
164 selected Large Language Model (LLM). The results will be evaluated using the  
165 Recall-Oriented Understudy for Gisting Evaluation (ROUGE).

166 By fostering mutual understanding, this tool aims to promote more effective and  
167 harmonious interactions across age groups, ultimately enhancing relationships and  
168 reducing miscommunication.

169 The main contributions of this study are as follows:

- 170 • Enhance linguistic understanding between generations by using fine-tuning  
171 a LLM to translate Gen Z slang to formal language, leveraging the strengths  
172 of advanced NLP techniques
- 173 • Bridge communication gaps between generations using the proposed model  
174 to foster better relationships
- 175 • Create a scalable framework that can be adapted to translate slang in other  
176 languages

## 1.2 Problem Statement

Internet slang fosters informal, relatable communication within the younger generation (Ghazali & Abdullah, 2021), especially Generation Z, but it presents challenges in understanding for people outside this demographic. The gap in comprehension with older generations widens as internet slang evolves, often leading to miscommunication affecting social relationships that contribute to the generational divide (Vacalares et al., 2023). A more specific translation tool developed using language models can be used to bridge this divide.

By leveraging the ability of LLM to generate a more nuanced and properly constructed answer, a better tool can be made to translate the slang into proper sentences. It has already been proven by the likes of GPT being modified and tailored for use in several automated chatbots to provide customer service. However, no such tool exists for slang translation of Generation Z, which arguably has the most diverse slangs compared to other generations. The creation of this tool will allow translating of such texts into formal sentences and help with bridging the generational divide between them and older people, especially teachers.

## 1.3 Research Objectives

### 1.3.1 General Objectives

This study aims to fine-tune the zephyr-7b LLM for use in the translation of Generation Z internet slang used by Filipinos in social media.

### 1.3.2 Specific Objectives

Specifically, the study aims to:

1. create a dataset of sentences containing Generation Z slang used in differing contexts and its formal translation,
2. create a LoRA implementation for fine-tuning an existing model,
3. fine-tune an existing LLM to translate sentences containing Generation Z slang into formal sentences, and
4. evaluate the performance of the trained model and compare it to the baseline model using several performance metrics.

## 1.4 Scope and Limitations of the Research

This study focused on the use of internet slang by Filipino Generation Z, with an emphasis on the English language, as it is widely used across various digital platforms, including social media. English has become a dominant medium of communication in the Philippines' digital landscape, particularly among younger demographics. According to a study by (?, ?), social media platforms serve as powerful tools for communicating in English as a second language, significantly influencing students' language use. The prevalence of English in social media facilitates learning opportunities and cross-cultural communication, highlighting its integral role in the digital communication practices of Filipino youth.

Furthermore, the extensive use of English on social media platforms reflects its

217 status as a marker of education and social standing in the Philippines. As noted  
218 by Mateo (2018) cited by (?, ?), the widespread use of English in social media  
219 underscores its significance in Filipino society, where proficiency in English is often  
220 associated with educational attainment and social mobility.

221 These findings underscore the importance of focusing on English in studies of in-  
222 ternet slang among Filipino Generation Z, as it remains a prevalent and influential  
223 language in their digital interactions.

## 224 1.5 Significance of the Research

225 This study contributes to the growing body of research on the evolving linguistic  
226 landscape shaped by the use of Internet slang, highlighting the communication  
227 practices of Generation Z. As digital platforms become increasingly central to  
228 daily interactions, Generation Z continues to develop and adopt informal linguistic  
229 expressions that reflect their identity, creativity, and cultural environment. While  
230 this form of communication enhances peer connectivity, it can also create barriers  
231 for individuals outside this demographic, particularly older generations.

232 The findings of this study offer practical benefits for various stakeholders. For edu-  
233 cators, the insights can support the development of more inclusive and responsive  
234 classroom communication strategies, enabling them to better understand and en-  
235 gage with their students' language use and cultural context. For parents, the study  
236 provides a framework for interpreting the language their children use online and  
237 in casual conversations, helping in bridging communication gaps and improving  
238 parent-child relationships. For media practitioners and digital marketers, under-

239 standing the patterns and meanings behind Gen Z slang can inform the creation of  
240 more relatable and culturally relevant content, enhancing audience engagement.

241 By addressing the communicative divide brought about by generational language  
242 differences, this research encourages a more informed approach to language vari-  
243 ation in contemporary digital spaces. Ultimately, the study underscores the im-  
244 portance of adapting to linguistic change in order to foster clearer, more effective  
245 intergenerational communication.

## Chapter 2

## Review of Related Literature

### 2.1 Communication Gap between Generations

Language is dynamic in nature and thus, constantly evolving over time. One example of this behavior is the development of internet slang. Internet slang is a result of language variation and is often regarded as informal (S. Liu, Gui, Zuo, & Dai, 2019). In the study, *The Use of Online Slang for Independent Learning in English Vocabulary* (Ambarsari, Amrullah, & Nawawi, 2020), students used internet slang to express their feelings and emotions, and to align their communication style with their peers.

However, this development has its challenges. It is suggested that younger generation should use slang to communicate with each other instead of older generations because it might cause confusion between them (Jeresano & Carretero, 2022).

This miscommunication is prominent between generations with differences in lin-

260 guistic familiarity as Suslak (Suslak, 2009) argues that age influences language  
261 use, noting that language evolves across generations. Supporting this, a study by  
262 Teng and Joo (Teng & Joo, 2023) found that the older a person is, the less likely  
263 they are to understand internet language.

264 Studies have shown that using internet slang improves relationships between those  
265 who use it. However, using internet slang for inter-generational communication  
266 can be a hindrance to proper and effective communication (Gonzaga, 2025).

## 267 **2.2 Generative AI**

268 Generative AI encompasses machine learning models that create new content,  
269 such as text, images, and audio, based on patterns learned from extensive data  
270 (Euchner, 2023). These models, including LLMs like those used in ChatGPT and  
271 Bing AI, use neural networks to predict the next word or phrase in a sequence,  
272 enabling them to generate human-like text (Brynjolfsson, Li, & Raymond, 2023).  
273 The ability of generative AI to understand and produce diverse content, ranging  
274 from creative writing code, makes it potentially useful for various applications,  
275 such as language translation (Fui-Hoon Nah, Zheng, Cai, Siau, & Chen, 2023).

## 276 **2.3 Existing Studies**

277 Zephyr-7b-beta has shown performance comparable to that of larger models, most  
278 notably, GPT-4 (Tunstall et al., 2023). This is further corroborated by the study  
279 by Vergho et al. (Vergho, Godbout, Rabbany, & Pelrine, 2024), which compared

multiple open-source LLMs with GPT-3.5 and GPT-4.0 models at that time. They found that zephyr-7b-beta is a viable open-source alternative to these models and is comparable with the latest GPT-4.0 model.

Khazeni et al. (Heydari, Albadvi, & Khazeni, 2024) used deep learning to create a model for translating Persian slang text into formal ones. The researchers explored the challenges of translating Persian slang into English within the context of film subtitling, specifically focusing on the performance of three neural machine translation (NMT) systems, namely Google Translate, Targoman, and Farazin. The primary interest of the paper lies in the understanding of how these NMT systems handle the complexities of slang translation. It was revealed that the NMT systems often struggle to capture the nuances of slang, leading to unnatural and inaccurate translations. Targoman performed best in naturalness, but it fell short of human translation quality. This implies the need for specialized algorithms or training data suitable for slang, and potentially human post-editing, to achieve accurate and culturally appropriate translations in this domain.

The study by Nocon et al. (Nocon, Kho, & Arroyo, 2018) explored translating Filipino colloquialisms, such as Conyo and Datkilab, into standardized Filipino, addressing comprehension barriers for non-familiar speakers. Two machine translation (MT) approaches were evaluated: Tensorflow’s Sequence-to-Sequence model using Recurrent Neural Networks (RNNs) and Moses’ Phrase-based Statistical MT. Moses outperformed Tensorflow on test data due to its handling of phrase combinations and unfamiliar words, while Tensorflow excelled on training data, indicating potential with refinement and more training data. The research underscores the need for robust datasets and highlights the strengths of phrase-based statistical MT in tackling slang translation challenges.

305 Ibrahim and Mustafa (Ibrahim & Sharief, 2023) developed a system to translate  
306 slang into formal language, addressing challenges posed by slang’s informality  
307 and variability. Using updated datasets of slang words, formal equivalents, and  
308 contextual sentences, they fine-tuned pre-trained models from Hugging Face’s  
309 Transformer library. While the T5-base model showed promise during training,  
310 it performed poorly in testing. In contrast, the “facebook/bart-base” model ex-  
311 celled, demonstrating high accuracy and low loss values. The study highlights the  
312 importance of fine-tuning and updating datasets for effective slang translation  
313 and emphasizes the potential of transformer models like “facebook/bart-base” in  
314 bridging informal and formal language gaps.

315 While general-purpose instruction tuning is now well-documented, less attention  
316 has been paid to fine-tuning LLMs for tasks involving informal or non-standard  
317 language such as slang. However, studies are emerging that suggest promising  
318 outcomes. For example, the SlangDIT benchmark (Liang, Meng, Wang, & Zhou,  
319 2025) developed a testbed specifically for slang understanding and translation, and  
320 preliminary findings indicate that even relatively small models fine-tuned on slang-  
321 rich datasets can rival zero-shot GPT-4 performance. This supports the notion  
322 that domain adaptation—particularly to informal linguistic domains—benefits  
323 substantially from task-specific training, even if the examples are synthetic. A  
324 study of Sun et al. (Sun, Hu, Gupta, Zemel, & Xu, 2024) also showed that  
325 even a small dataset of slang sentences helped GPT 3.5 perform better than zero-  
326 shot GPT-4.0 at slang detection. While it is a classification task, this suggests  
327 a promising approach to improve the performance of LLMs in slang translation  
328 tasks.

## 2.4 LoRA for Fine Tuning

Low Rank Adaptation, or LoRA, is an efficient Parameter Efficient Fine Tuning (PEFT) method proposed by Hu et al (Hu et al., 2021). This can significantly decrease the required storage for training while producing comparable results and in some cases even outperforming other adaptation methods. In addition, it has minimal chance of catastrophic forgetting as the original weights are not being tampered with, unlike other fine-tuning methods. These factors make it a suitable option for slang translation as a quick yet accurate solution. In a study conducted by Zhao et al. (Zhao et al., 2024), they determined that some LLMs using LoRA for fine tuning can outperform GPT-4, one of the most advanced LLM models currently. A study by Nguyen et al. (Nguyen, Wilson, & Dalins, 2023) used LoRA in fine tuning a pre-trained Llama 2 7B model for text classification of a dataset that contains slang. They were able to create a more accurate model compared to models by existing studies at that time.

## 2.5 Data Augmentation through Synthetic Data Generation

Datasets specifically of slang sentences are hard to come by especially ones dedicated to a certain group. This is where synthetic data generation comes into play. Modern LLMs fine-tuning leverages synthetic data generation in many ways. A good example of which is the model we are using, zephyr-7b-beta. This model is fine-tuned from Mistral 7B and was trained on ultrachat dataset (Tunstall et al.,

2023), which is a synthetic dataset from data obtained from the Internet (Ding et al., 2023). In addition, the model showed performance comparable to larger open-source models in language tasks.

Synthetic data on its own is not enough to create a model that can perform well in slang translation tasks. A study by Liang et al. (Liang et al., 2025) showed that even a small dataset of slang sentences can help improve the performance of LLMs in slang translation tasks. This suggests that domain adaptation, particularly to informal linguistic domains, benefits substantially from task-specific training, even if the examples are synthetic. Nadas et al. (Nadas, Diosan, & Tomescu, 2025) also showed that synthetic data generation can be used to create a synthetic dataset. The measures they used made sure that the dataset is almost as good as a dataset of real slang sentences, especially when augmenting a small dataset. This is particularly useful for slang translation tasks, where datasets are often limited and hard to come by.

## 2.6 Evaluation Metrics

Automatic evaluation metrics are essential for assessing the performance of machine translation systems, especially in the context of slang translation. These metrics provide a quantitative measure of translation quality, allowing for efficient comparison between different models and approaches. Commonly used metrics include BLEU (Bilingual Evaluation Understudy) and ROUGE (Recall-Oriented Understudy for Gisting Evaluation). BLEU measures the overlap between the machine-generated translation and one or more reference translations, focusing

on n-gram precision (Papineni, Roukos, Ward, & Zhu, 2001). ROUGE, on the other hand, evaluates the quality of summaries by comparing them to reference summaries, emphasizing recall and precision (Lin, 2004). For slang translation, these metrics can be particularly useful in assessing how well a model captures the nuances and informal expressions characteristic of slang. However, it is important to note that while these metrics provide valuable insights, they may not fully capture the semantic richness and cultural context inherent in slang expressions (Liang et al., 2025). Therefore, human evaluation is often recommended to complement automatic metrics, ensuring a more comprehensive assessment of translation quality. As such, a pairwise comparison of the generated translations against a reference translation is often used to evaluate the performance of LLMs, as it is done with other studies (Zhao et al., 2024)(Chiang et al., 2024). This method allows for a more nuanced understanding of how well a model captures the informal expressions and cultural context inherent in slang, providing a more comprehensive assessment of translation quality.

## 2.7 Chapter Summary

This chapter shows how generational differences create communication gaps, especially due to internet slang. Younger people tend to use slang to express emotions and connect with friends, but this can confuse older generations who aren't as familiar with these terms. Research shows that as language changes over time, older people are generally less likely to understand the newest internet language. To bridge this gap, some recent studies have utilized machine learning to translate slang into more standard language. For instance, Khazeni et al. (Heydari et al.,

2024) used deep learning to translate Persian slang, while Nocon et al. (Nocon et  
al., 2018) created a Filipino slang translator using statistical models. Moreover,  
Ibrahim and Mustafa (Ibrahim & Sharief, 2023) fine-tuned pre-trained models to  
learn slang meanings. One promising technique for this is Low Rank Adaptation  
(LoRA), which is a fine-tuning method that keeps the original model stable while  
using less storage. Studies by Zhao et al. (Zhao et al., 2024) and Nguyen et al.  
(Nguyen et al., 2023) show that LoRA models are not only efficient but can even  
outperform advanced models like GPT-4 when it comes to slang translation and  
text classification. However, datasets specifically for slang translation are often  
limited, making synthetic data generation a valuable tool.

Table 2.1: Summary of Existing Studies

Author	Focus	Gaps	Problem Solved
Nocon et al.	Developing machine translators for Filipino colloquialisms using sequence-to-sequence models and statistical machine translation (Moses).	Tensorflow models had issues with unknown tokens and repetitions, and limited ability to generalize to unseen data.	Demonstrated the feasibility of machine translation for Filipino colloquialisms, with Moses as a viable solution.
Ibrahim et.al	Developing an intelligent system to transform English slang words into formal words.	The study noted that more powerful processors could improve the training and testing, and that previous datasets were outdated and needed updating.	Demonstrated an effective model for translating English slang to formal English and highlighted the importance of fine-tuning pre-trained models.
Khazeni et al.	Persian slang text conversion to formal and deep learning of Persian short texts on social media	The BERT models used did not align well with the informal data used in the sentiment analysis.	Created a tool to convert Persian slang to formal text and improved sentiment analysis of short texts using deep learning.

## Chapter 3

# Research Methodology

This chapter lists and discusses the specific steps and activities that will be performed to accomplish the project. The discussion covers the activities from pre-proposal to Final SP Writing.

### 3.1 Research Activities

Figure 3.1: Summarized Methodology

### 411 3.1.1 Data Gathering

412 A dataset of sentences containing Generation Z slang and its formal translation  
413 was used in this study. This dataset was created using several source: data ob-  
414 tained from social media posts and manually translated by the researchers, exist-  
415 ing datasets from HuggingFace, and machine generated and translated sentences  
416 using GPT-4o from OpenAI.

417 The data obtained from social media posts were from verified users of X whose  
418 ages are within the Generation Z, so that the dataset is accurate. The data was  
419 manually translated by the researchers to ensure that the translation is accurate  
420 and reflective of the target demographic. Data obtained from existing datasets  
421 and GPT-4o was checked manually to check if whether the sentence is one used  
422 by Generation Z. These processes ensured that the dataset is of high quality and  
423 representative of what and how Generation Z slang is used.

### 424 3.1.2 Data Preprocessing

425 The dataset used for the fine-tuning of the model was preprocessed to ensure opti-  
426 mal performance of the model. Unnecessary information such as email addresses  
427 and URLs was removed. The data was then manually cleaned up to remove  
428 unnecessary characters such as emojis and fixed issues such as typos. A simi-  
429 lar approach was done with existing and machine generated datasets to ensure  
430 consistency within the training dataset.

431 The dataset is then split into train and test datasets in a 90/10 ratio to maximize  
432 the data learned by the model without compromising on the model's ability to

433 generalize to new data. The train dataset is then split again into a 90/10 ratio  
434 to ensure no overfitting while still allowing the model to adapt to the pattern  
435 of slang. The cleaned up dataset was then tokenized through the Transformers  
436 library provided by HuggingFace as the library already has tokenizers available  
437 for their pretrained models. This ensures that the data is formatted properly as  
438 required by the model to be used.

### 439 3.1.3 Model Fine-Tuning

440 The model used in this study was zephyr-7b-beta because it is open-source and  
441 was proven to perform better than other models of the same size. In addition, it  
442 can be trained in a GPU with 16GB of VRAM, necessary as we are using the free  
443 plan of Google Colab as the platform of choice for prototype fine-tuning of the  
444 model. However, during the training process with the full dataset, the Pro+ plan  
445 of Google Colab was used for faster training time and background execution of the  
446 training process, allowing the training to continue uninterrupted regardless of the  
447 network connection. This study used the example codes provided by HuggingFace  
448 in the documentation of their various libraries and sample notebook provided in  
449 the zephyr-7b-beta repository.

450 The model was loaded using the Transformers library and was quantized into 4  
451 bits through BitsandBytes library to fit the entire model in the allocated resources  
452 while having enough headroom for training. In addition, the Unsloth library was  
453 used to speed up the training time and reduce the resources used even more  
454 (Daniel Han & team, 2023). A LoRA adapter was then attached to the model to  
455 further reduce the parameters to be trained.

456 To evaluate the model training process and ensure that the model is not overfit-  
457 ting, BLEU and ROUGE will be used. These metrics use n-grams, making them  
458 superior to standard recall and precision metrics as they take into account the  
459 positioning of the words. These two metrics were implemented using the Evaluate  
460 library by HuggingFace, making it easier to integrate with the rest of the model  
461 training process. These metrics was calculated at every epoch of the training  
462 process and is used for an early stopping callback to immediately stop the model  
463 training if the model seems to be overfitting.

464 The model was then trained using SFTTrainer class from the Transformer Rein-  
465 forcement Learning (TRL) library of HuggingFace to simplify the training process  
466 (von Werra et al., 2020). The model was trained with the following parameters:  
467 optimizer is paged 4bit AdamW, batch size of 8, learning rate of 2e-5, and maxi-  
468 mum number of epochs of 50. These parameters were chosen based on the GPU  
469 provided in Colab, the test notebook by HuggingFace and the default parameters  
470 of SFTTrainer.

#### 471 3.1.4 Model Evaluation

472 The model was evaluated using both automatic and manual evaluation metrics.  
473 Identical answers and answers with minimal difference, such as punctuation, be-  
474 tween the fine-tuned and the base model were removed in the test set to ensure  
475 that the model is evaluated properly. After filtering, a total of 143 sentences  
476 were used to evaluate the model. The model was then prompted to generate a  
477 formal sentence for 170 sentences in the test dataset. The generated sentences  
478 were then compared to the formal translation of the sentence using BLEU and

479 ROUGE metrics. The base zephyr-7b-beta model was also prompted to gener-  
480 ate sentences for the BLEU and ROUGE metric and the pairwise comparison for  
481 human evaluation.

482 An online survey was conducted using Google Forms to compare the outputs of the  
483 fine-tuned model and the base model in order to evaluate the effectiveness of the  
484 fine-tuning process. Participants were presented with sentence pairs generated  
485 by both models and were asked to choose the more accurate translation of a  
486 given Generation Z slang sentence based on accuracy, naturalness, and contextual  
487 appropriateness. To minimize potential ordering bias, the sequence in which the  
488 outputs from the two models were displayed was randomized for each pair. The  
489 researchers implemented a Split Questionnaire Design (SQD) by dividing the full  
490 survey into multiple sets to improve response rates and reduce respondent fatigue  
491 (?). A total of 143 questions was unevenly distributed into six forms. In  
492 addition, the number of responses per form varied which leads to an unbalanced  
493 results with some items being evaluated more than others.

494 To address these challenges, aggregated weighted average was utilized. In weighted  
495 average, the results of each form was weighted so that responses are represented  
496 proportionately (Ganti, 2024). Specifically, the responses to each item were first  
497 summarized using their average scores. These scores were then weighted by the  
498 number of respondents per item to account for variations in form size and respon-  
499 dent count. This weighting approach allowed us to combine results from the six  
500 forms in a way that gave appropriate emphasis to the sample size behind each  
501 item’s score, providing a fair and interpretable basis for comparison across all 143  
502 questions.

503 This method offered a simple yet effective way to integrate responses from an SQD  
504 structure without requiring overlap or complex modeling assumptions. It also  
505 ensured that items answered by more respondents contributed more substantially  
506 to the overall evaluation while avoiding bias from unequal form lengths.

## Chapter 4

# Results and Discussions

### 4.1 Dataset

We built a dataset containing a total of 1155 Gen Z internet slang sentences and their corresponding formal translations. The created dataset was then combined with another dataset from Hugging Face that contains 548 Gen Z internet slang and their corresponding formal translation for a total of 1703 sentence pairs. The dataset was then split into training, validation, and test sets with a ratio of 81:9:10. The training set contains 1380 sentence pairs, the validation set contains 153 sentence pairs, and the test set contains 170 sentence pairs. The dataset was then tokenized using the tokenizer of the base model, zephyr-7b-beta, to prepare it for training. The tokenized dataset was then saved in a JSON format to be used for training the model.

## 4.2 Model Evaluation

### 4.2.1 Model Training

The model was trained for 7 epochs before the early stopping callback was triggered because the evaluation metrics has not improved by at least 0.01 for 3 consecutive epochs. This prevented the overfitting seen in the following figure. Figure 4.1 shows that the training loss is decreasing and in Figure 4.2 the validation loss is increasing and other metrics are not improving. These indicate that the model is overfitting to the training data and may not generalize well to new data. The model training was stopped in just 7 epochs and the best model amongst the epochs, the one with the lowest validation loss and highest metrics, was chosen as the final model.

Figure 4.1: Training loss curve of the fine-tuned model across training steps

Figure 4.2: Evaluation loss curve of the fine-tuned model across training steps

Figure 4.3: Evaluated using BLEU metric

Figure 4.4: Evaluated using ROUGE-L metric

### 531 4.2.2 Text Generation

532 A total of 170 sentences were translated using both the base zephyr-7b-beta model  
 533 and the finetuned model. The translations are then filtered to remove duplicate  
 534 answers between models or has minor differences such as punctuation or filler  
 535 words that does not contribute to the meaning of the sentence. A total of 143  
 536 sentences then served as the dataset used to evaluate the performance of the model  
 537 and comparing it with the other base model.

### 538 4.2.3 Automatic Evaluation Metrics

539 The dataset was automatically evaluated using BLEU and ROUGE metrics, specif-  
 540 ically the ROUGE-L metric as the dataset do not contain newlines that ROUGE-  
 541 Lsum uses to separate the input with. These scores were then averaged to deter-  
 542 mine the score of the models. The base model obtained a BLEU score of 0.8099

543 and ROUGE-L Score of 0.8336 and the fine-tuned model obtained a BLEU score  
544 of 0.8151 and ROUGE-L Score of 0.8396. While the difference between the mod-  
545 els is minimal, this does not completely represent the performance of the models  
546 as these metrics are only used to determine if the generated text is close to the  
547 reference text, regardless of the context and the overall quality of the generated  
548 text. However, it does show that the fine-tuned model has little improvement over  
549 the base model.

#### 550 4.2.4 Manual Evaluation Metrics

551 A manual evaluation was conducted by the researchers through a survey admin-  
552 istered via Google Forms to determine which of the two models is preferred by  
553 Generation Z students at University of the Philippines Visayas (UPV). The sur-  
554 vey comprised a total of 144 questions, which were distributed across five sepa-  
555 rate forms. The first form contained 20 questions, the second 19, the third 20,  
556 the fourth 20, the fifth 14, **and the sixth 50 amounting to 143 questions**  
557 in total. Each question presented two translation options: one generated by the  
558 fine-tuned model and the other by the base model. Respondents were asked to  
559 select the translation they preferred in each case. **A total of 114 individu-**  
560 **als participated in the survey, with 29, 22, 22, 21, and 20 respondents**  
561 **completing Forms 1 through 5, respectively.**

562 The data presented below illustrate respondent preferences between the base and  
563 fine-tuned models across the six survey forms, as well as the overall summary of  
564 the results. Each graph visualizes the outcomes for an individual form, specifically  
565 indicating both the raw number of responses and the corresponding percentages

566 favoring each model. A systematic evaluation for each graph is provided as follows:

Figure 4.5: Form 1 Evaluation

567 Figure 4.5 shows that among the 29 respondents, 306 responses or 52.8 percent pre-  
568 ferred the base model, while 274 responses or 47.2 percent favored the fine-tuned  
569 model. This indicates a slight preference for the base model in this particular  
570 form. Notably, this result deviates from the overall trend observed in the other  
571 four forms, where the fine-tuned model tends to be favored. Form 1 is the only  
572 instance in which the base model outperformed the fine-tuned model, suggesting  
573 that specific characteristics of this form may have influenced the preferences of  
574 the respondents.

575 Figure 4.6 implies that among 22 respondents, 236 responses, or 56.5 percent,  
576 favored the fine-tuned model, while 182 responses, or 43.5 percent, preferred the  
577 base model. This 13 percent margin reflects the clear preference for the fine-tuned  
578 model, which is consistent with the overall trend observed across the other forms.

Figure 4.6: Form 2 Evaluation

Figure 4.7: Form 3 Evaluation

579 Figure 4.7 illustrates that among the 22 respondents, the fine-tuned model received  
580 a significantly higher preference, with 259 responses or 60.2 percent, compared to  
581 the base model with 171 responses or 29.8 percent. This 20.4 percent margin  
582 represents the widest gap among all forms. This strongly indicates the superior  
583 performance of the fine-tuned model on translating, presented in Form 3.

Figure 4.8: Form 4 Evaluation

584 Figure 4.8 highlights that the 21 respondents in Form 4 yielded a nearly even  
585 distribution of preferences, with 218 responses or 51.9 percent favoring the fined-  
586 tuned model and 202 responses or 48.1 percent preferring the base model. This  
587 narrow 3.8 percent difference suggests a comparable level of performance between  
588 the two models in this particular form.

589 Figure 4.9 conveys that among the 20 respondents in Form 5, 152 responses or  
590 54.3 percent selected the fine-tuned model, while 128 responses or 45.7 percent  
591 chose the base model. This 8.6 percent margin reinforces the general trend toward

Figure 4.9: Form 5 Evaluation

the fine-tuned model across all forms.

Figure 4.10 indicates the results of the sixth form. 21 respondents in Form 6 showed a slight preference for the base model, garnering 52.5%, over the fine-tuned model, with 47.5%. Along with Form 1, this result contrasts with the overall trend observed across all gathered data.

Figure 4.11 presents the overall summary across all five forms, with a total of 135 responsees garnered in the survey. In total, the fine-tuned model received 53.5%, while the base model garnered 989 preferences or 46.5%. The resulting 7% margin between the two model indicates a moderate overall preference among Gen Z students at UPV for the fine-tuned model, suggesting its relatively better performance in meeting the participants' expectations for translation quality.

Figure 4.10: Form 6 Evaluation

Figure 4.11: Summary Evaluation

## 603 4.3 Summary

604 The chapter presented the evaluation results and discussions on the performance  
605 of the fine-tuned language model for translating Gen Z internet slang into their  
606 formal translations. The dataset used for training consisted of 1,703 sentence  
607 pairs, combining original and publicly available data. The model was trained  
608 for seven epochs, with early stopping employed to prevent overfitting, which was  
609 evident from the divergence between training and validation losses.

610 Evaluation was conducted using both automatic and manual methods. The auto-  
611 matic evaluation, using BLEU and ROUGE-L metrics, showed marginal improve-  
612 ments in the fine-tuned model compared to the base model, suggesting slightly  
613 better alignment with reference translations.

614 To support the results of automatic evaluation metrics, a manual evaluation was  
615 carried out through online surveys among Generation Z students at UPV. Partic-  
616 ipants compared translations from both models across six forms. Results showed  
617 a moderate overall preference for the fine-tuned model, with 53.5% of responses  
618 in its favor. While one form showed a slight preference for the base model, the  
619 fine-tuned model was generally preferred, especially in Form 3 where it showed  
620 the largest margin.

621 In summary, the findings indicate that the fine-tuned model slightly outperformed  
622 the base model in terms of automatic metrics and showed a modest but consistent  
623 preference among target users, supporting its effectiveness in translating Gen Z  
624 slang into more formal language.

## Chapter 5

## Conclusion

In this study, we constructed a dataset, containing 1,703 pairs of Gen Z internet slang sentences and their corresponding formal translations. We fine-tuned a zephyr-7B-Beta model and evaluated its performance against the base model. Model training was stopped early to prevent overfitting, and the best model was selected based on validation performance. Both automatic and manual evaluation methods were employed to assess translation quality. Automatic metrics, using BLEU and ROUGE-L, showed that the fine-tuned model slightly outperformed the base model with scores of 0.8151 and 0.8396. Manual evaluation, conducted via online surveys with Generation Z students at UPV, indicated a moderate overall preference for the fine-tuned model, which received 53.5% of the total responses. These results suggest that while the improvement in performance was not drastic, the fine-tuned model better aligned with the expectations and preferences of the target demographic.

## 5.1 Limitations

Language is dynamic and constantly evolving, making it difficult to establish clear boundaries on when slang terms emerge or fade within a generation. Additionally, the dataset created for this study was relatively small, and the number of evaluators involved was limited. In addition, as stated in Section 3.1.3, the computational constraints posed a challenge—loading a model with 7 billion parameters requires approximately 66 GB of memory, while Google Colab provided 16GB of VRAM which is insufficient for high-capacity models.

## 5.2 Recommendations

Future researchers are encouraged to expand the vocabulary of slang terms used on the Internet and explore more recent trends, taking into account the dynamic nature of language. It is also recommended that future studies utilize a larger and more diverse dataset to improve the robustness of the findings.
